Scientific Programming Practical 2

Introduction

Modules and Objects

Modules are text files with .py extension

python3 exercise1.py

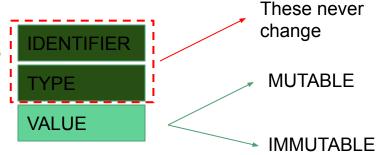

Import modules to use them

```
import math
A = math.sqrt(4)
print(A)
2.0
```

Objects

"Objects are Python's abstraction for data. All data in a Python program is represented by objects or by relations between objects."

More on this later on in the course

Built-in data types

Type	Meaning	Domain	Mutable?
bool	Condition	True, False	No
int	Integer	$\{-2^{-63}, \dots, 2^{63} - 1\}$ \mathbb{Z}	No
long	Integer	Z	No
long	Integer	\mathbb{Z}	No
float	Rational	Q (more or less)	No
str	Text	Text	No
list	Sequence	Collections of things Yes	
tuple	Sequence	Collections of things No	
dict	Map	Maps between things Yes	

Variable assignment

What happens when we...

>>> sides = 4

A new object is created and the name 'sides' points to it (i.e. it is a reference in the Namespace)

ID:10915392

type: INT

value: 4

```
sides = 4
print( type(sides) )
print( id(sides) )

<class 'int'>
10915392
```

INT is **immutable**, therefore:

```
sides = 4 #a square
print ("value:", sides, " type:", type(sides), " id:", id(sides))
sides = 5 #a pentagon
print ("value:", sides, " type:", type(sides), " id:", id(sides))

value: 4 type: <class 'int'> id: 10915392
value: 5 type: <class 'int'> id: 10915424
```

Name of variables

You can choose the name you like but:

- Can only contain A-Z, a-z, 0-9 or _
 i.e. no +, -, ; etc. allowed
- 2. Cannot start with a number
- 3. Cannot be one of the reserved words

and	as	assert	break	class	continue
def	del	elif	else	except	exec
finally	for	from	global	if	import
in	is	lambda	nonlocal	not	or
pass	raise	return	try	while	with
yield	True	False	None		

Integers

As one would expect...

```
a = 7
b = 4

a + b # 11
a - b # 3
a // b # integer division: 1
a * b # 28
a ** b # power: 2401
a / b # division 0.8333333333333334
type(a / b)
```

REMEMBER: **Immutable**Their range is limited ONLY by the AVAILABLE memory

Variable assignment: question for you

What happens when we execute the following code...

```
>>> value = 10
>>> print(id(value))
>>> print(type(value))
>>> print(value)
```

```
>>> value = value + 1
>>> print(id(value))
>>> print(type(value))
>>> print(value)
```

Variable assignment: question for you

What happens when we execute the following code...

```
>>> value = 10
>>> print(id(value))
>>> print(type(value))
>>> print(value)
```

```
>>> value = value + 1
>>> print(id(value))
>>> print(type(value))
>>> print(value)
```

ID:10914784

type: INT

value: 10

ID:10914816

id(11)

type: INT

value: 11

Booleans

Assume only values True and False

```
a = bool(1)
b = bool(0)
c = bool(72)
d = bool(-5)
t = int(True)
f = int(False)

print("a: ", a, " b: ", b, " c: ", c, " d: ", d , " t: ", t, " f: ", f)
a: True b: False c: True d: True t: 1 f: 0
```

Boolean algebra rules...

```
T = True
F = False

print ("T: ", T, " F:", F)

print ("T and F: ", T and F) #False
print ("T and T: ", T and T) #True
print ("F and F: ", F and F) #False
print ("not T: ", not T) # False
print ("not F: ", not F) # True
print ("T or F: ", T or F) # True
print ("T or T: ", T or T) # True
print ("F or F: ", F or F) # False
```

All numbers evaluate to **True**, **except 0**.

Reals

In python they are floating points (floats). 64 bits of information divided in sign, exponent (11bits) and mantissa (52 bits).

Example: Let's calculate the area of the center circle of a football pitch (radius = 9.15m) recalling that $area = Pi * R^2$:

```
In [11]: R = 9.15
Pi = 3.1415926536
Area = Pi*(R**2)
print (Area)

263.02199094102605
```

Use parenthesis or remember precedence of operators...

**	Power (Highest precedence)	
+,- Unary plus and minus		
* / // % Multiply, divide, floor division,		
+ -	Addition and subtraction	
<= < > >=	Comparison operators	
!-	Equality operators	
not or and Logical operators (Lowest precede		

In python they are **immutable objects** that are used to represent and work with text.

They contain unicode characters (that can also represent formatting like newline \n, tab \t ...

```
S = "my first string, in double quotes"
S1 = 'my second string, in single quotes'
S2 = '''my third string is
in triple quotes
therefore it can span several lines'''
S3 = """my fourth string, in triple double-quotes
can also span
several lines"""
print(S, '\n') #let's add a new line at the end of the string with \n
print(S1, '\n')
print(S2, '\n')
print(S3, '\n')
my first string, in double quotes
my second string, in single quotes
my third string is
in triple quotes
therefore it can span several lines
my fourth string, in triple double-quotes
can also span
several lines
```

Escape special characters

11	Backslash	
\n	ASCII linefeed (also known as newline)	
\t	ASCII tab character	
1,	Single quote	
/"	Double quote	
\xxxx/	Unicode character xxxx (hexadecimal)	

```
myString = "This is how I \'quote\' and \"double quote\" things in strings"
print(myString)
```

This is how I 'quote' and "double quote" things in strings

```
print("Greek omega is: \u03C9")
Greek omega is: ω
```

Functions and operators

Result	Operator Meaning		
int	len(str)	Return the length of the string	
str	str + str	Concatenate two strings	
str	str * int	Replicate the string	
bool	str in str	Check if a string is present in another string	
str	str[int]	Read the character at specified index	
str	str[int:int]	Extract a sub-string	

Result	Operator	Meaning	
int	len(str)	Return the length of the string	
str	str + str	Concatenate two strings	
str	str * int	Replicate the string	
bool	str in str	Check if a string is present in another string	
str	str[int]	Read the character at specified index	
str	str[int:int]	Extract a sub-string	

Example A tandem repeat is a short sequence of DNA that is repeated several times in a row. Let's create a string representing the tandem repeat of the motif "ATTCG" repeated 5 times. What is the length of the whole repetitive region? Is the motif "TCGAT" (m1) present in the region? The motif "TCCT" (m2)? Let's give an orientation to the tandem repeat by adding the string "5'-" (5' end) on

the left and "-3" (3' end) to the right.

```
motif = "ATTCG"

tandem_repeat = motif * 5

print(motif)
print(tandem_repeat, " has length", len(tandem_repeat))
m1 = "TCGAT"
m2 = "TCCT"

print("Is ", m1, " in ", tandem_repeat, " ? ", m1 in tandem_repeat )
print("Is ", m2, " in ", tandem_repeat, " ? ", m2 in tandem_repeat )
oriented_tr = "5\'-" + tandem_repeat + "-3\'"
print(oriented_tr)
```

ATTCG
ATTCGATTCGATTCGATTCG has length 25
Is TCGAT in ATTCGATTCGATTCGATTCGATTCG ? True
Is TCCT in ATTCGATTCGATTCGATTCG ? False
5'-ATTCGATTCGATTCGATTCG-3'

Indexing and Slicing

Indexing starts from 0

str[i]: i+1-th character
str[S:E:step] slice string

Remember:

S inclusive, E exclusive, step is optional

```
0 1 2 3 4 5 6 7 8 9 10 11 12 13

L u t h e r C o I I e g e

-14 -13 -12 -11 -10 -9 -8 -7 -6 -5 -4 -3 -2 -1
```

```
S = "Luther College"
print(S) #print the whole string
print(S == S[:]) #a fancy way of making a copy of the original string
print(S[0]) #first character
print(S[3]) #fourth character
print(S[-1]) #last character
print(S[0:6]) #first six characters
print(S[-7:]) #final seven characters
print(S[0:len(S):2]) #every other character starting from the first
print(S[1:len(S):2]) #every other character starting from the second
Luther College
True
h
Luther
College
Lte olg
uhrClee
```

Methods

Method	Meaning	
str.upper()	Return the string in upper case	
str.lower()	Return the string in lower case	
str.strip(str)	Remove strings from the sides	
str.lstrip(str)	Remove strings from the left	
str.rstrip(str)	Remove strings from the right	
str.replace(str, str)	Replace substrings	
str.startswith(str)	Check if the string starts with another	
str.endswith(str)	Check if the string ends with another	
str.find(str)	Return the first position of a substrin starting from the left	
str.rfind(str)	Return the position of a substring starting from the right	
str.count(str)	Count the number of occurrences of a substring	
	str.upper() str.lower() str.strip(str) str.lstrip(str) str.rstrip(str) str.replace(str, str) str.startswith(str) str.endswith(str) str.find(str) str.rfind(str)	

IMPORTANT NOTE Since Strings are immutable, every operation that changes the string actually produces a new *str* object having the modified string as value.

Example: Given the DNA sequence S = "aTATGCCCATatcgctAAATTGCTGCCATTACA". Print its length (removing any blank spaces at either sides), the number of adenines, cytosines, guanines and thymines present. Is the sequence "ATCG" present in S? Print how many times the substring "TGCC" appears in S and all the corresponding indexes.

```
5 = "
        aTATGCCCATatcgctAAATTGCTGCCATTACA
print(S)
S = S.strip("")
print(S)
print(len(S))
tmpS = S.upper() #for simplicity to count only 4 different nucleotides
print("A count: ", tmpS.count("A"))
print("C count: ", tmpS.count("C"))
print("T count: ", tmpS.count("T"))
print("G count: ", tmpS.count("G"))
print("Is ATCG in ", tmpS, "? ", tmpS.find("ATCG") != -1) #or tmpS.count("ATCG") > 0
print("TGCC is present ", tmpS.count("TGCC"), " times in ", tmpS)
print("TGCC is present at pos ", tmpS.find("TGCC"))
print("TGCC is present at pos ", tmpS.rfind("TGCC")) #or tmpS.find("TGCC".4)
   aTATGCCCATatcgctAAATTGCTGCCATTACA
aTATGCCCATatcgctAAATTGCTGCCATTACA
33
A count: 10
C count: 9
T count: 10
G count: 4
Is ATCG in ATATGCCCATATCGCTAAATTGCTGCCATTACA ? True
TGCC is present 2 times in ATATGCCCATATCGCTAAATTGCTGCCATTACA
TGCC is present at pos 3
TGCC is present at pos 23
```

Example: Since the genetic code is degenerate, there are many codons encoding for the same aminoacid. Consider Proline, it can be encoded by the following codons: CCU, CCA,CCG, CCC. Let's create a string proline and assign it to its possible codons one after the other.

Remember:

strings are immutable and do not support item assignment

```
"""
Wrong solution. We cannot directly replace the value of a string
proline = "CCU"
print("Proline can be encoded by: ", proline)
proline[2]="A"
print(".. or by: ", proline)
```

Example: Since the genetic code is degenerate, there are many codons encoding for the same aminoacid. Consider Proline, it can be encoded by the following codons: CCU, CCA,CCG, CCC. Let's create a string proline and assign it to its possible codons one after the other.

Remember:

strings are immutable and do not support item assignment

```
"""
Wrong solution. We cannot directly replace the value of a string
"""
proline = "CCU"
print("Proline can be encoded by: ", proline)
proline[2]="A"
print(".. or by: ", proline)
```

Proline can be encoded by: CCU

Example: Since the genetic code is degenerate, there are many codons encoding for the same aminoacid. Consider Proline, it can be encoded by the following codons: CCU, CCA,CCG, CCC. Let's create a string proline and assign it to its possible codons one after the other.

Remember:

strings are immutable and do not support item assignment

```
correct solution. Using str.replace
proline = "CCU"
print("Proline can be encoded by: ", proline)
proline = proline.replace("U", "A")
print(".. or by: ", proline)
proline = proline.replace("A", "G")
print(".. or by: ", proline)
proline = proline.replace("G", "C")
print(".. or by: ", proline)
```

Proline can be encoded by: CCU

.. or by: CCA .. or by: CCG .. or by: CCC

Example: Since the genetic code is degenerate, there are many codons encoding for the same aminoacid. Consider Proline, it can be encoded by the following codons: CCU, CCA,CCG, CCC. Let's create a string proline and assign it to its possible codons one after the other.

Remember:

strings are immutable and do not support item assignment

```
Another correct solution. Using string slicing and catenation.

"""

proline = "CCU"

print("Proline can be encoded by: ", proline)

proline = proline[:-1]+"A" #equal to proline[0:-1] or proline[0:2]

print(".. or by: ", proline)

proline = proline[:-1]+"G"

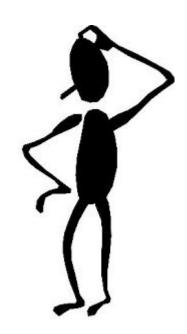

print(".. or by: ", proline)

proline = proline[:-1]+"C"

print(".. or by: ", proline)
```

Proline can be encoded by: CCU
.. or by: CCA
.. or by: CCG
.. or by: CCC

Questions?

https://qcbsciprolab2019.readthedocs.io/en/latest/practical2.html

Go quickly through the text and do the exercises at the end

Exercises

1. An exon of a gene starts from position 12030 on a genome and ends at position 12174. Does an A/T SNP present at position 12111 affect this exon? And what about a SNP present at position 12188?

Show/Hide Solution

- 2. SNP FB_AFFY_0000024 of the Apple 480K SNP chip has 5' flanking region (i.e. the forward probe) CATTATTTTCACTTGGGTCGAGGCCAGATTCCATC and 3' flanking region (i.e. reverse probe) GGATTGCCCGAAATCAGAGAAAAGTCG. The SNP is a G/A transversion. Answer the following questions:
 - 1. What is the length of the 5' flanking region? And that of the 3' flanking region?
 - 2. The IUPAC code of the G/A transversion is R. What is the sequence of the whole region using the [G/A] notation for the SNP (hint: concatenate in a new string called *region*) and the iupac notation R (region_iupac)?
 - 3. Retrive and print only the SNP from region and jupac_region

Show/Hide Solution

3. Compute the melting temperature T_m of the primer with sequence "TTAGCACACGTGAGCCAATGGAGCAAACGGGTAATT". The melting temperature T_m (in degrees Celtius) can be computed as: $T_m = 64.9 + 0.41(GC - 16.4)/N$, where GC is the total number of G and C in the primer and N is its length.

Show/Hide Solution
